Kunal Matthews	amos-m2345@csu.fullerton.edu
Don Feng	donfeng97@csu.fullerton.edu

## 2 Introduction

This document details the outcomes of the tests performed on different modules of the system and whether any unexpected behaviors were detected.

### 2.1 Identification

Software Revision Tested:	1.0
Revision Release Date:	April 28, 2019

## 3 Test Results

<put some lead in text here>

### **3.1 Test Case 1 Results**

Description: Test the data retrieved from Zillow's situation.

Bugs Found:

- 1) Internet connection fail, causing the function stopped (name or service not known)
- 2) The input value is not valid (city name not exist in dataset)

## 3.2 Test Case 2 Results

Description: Test the input and output of the User Interface and server communication

Bugs Found:

- 1) Invalid data: If input data doesn't match valid location a junk value will be returned and will not be accurate.
- 2) No input: Predictor model will fail, and an error will return in the python console.
- 3) Server error: server is in infinite wait cycle.

### 3.3 Test Case 3 Results

Description: Test the behavior of the predictor module on different levels against the \$ 3.0 threshold on a random subset of size 100 with an initial seed of 23.

Bugs Found:

- 1) None: all the predictors behave correctly on the designated dataset

Potential Hazards:

- 1) The neighborhood level predictor once fully loaded required more than 32 GB of memory. This could slow down or potentially crash machines without sufficient amount of resources.
- 2) The input to the model must be consistent. Note that an inconsistent input still goes through the chain of models. However, the output is garbage and should be ignored.
